Objective

Geo-Location Routing Policy in AWS Route 53 is a routing policy that allows you to direct traffic to different resources based on the geographic location of the user making the request. This is useful when you want to provide a better user experience by serving content from the nearest or most relevant resource based on the user's location, such as directing traffic to a specific data center, region, or server.

Here's how it works:

1. Geo-location: You specify geographic regions (like countries, continents, or specific cities), and Route 53 uses the IP address of the user making the request to determine their location.
2. Routing: Based on that location, you can route the request to different endpoints. For example, you could direct users in North America to one server and users in Europe to another, improving performance and latency.
3. Fallback Options: You can define default or fallback records to be used when there's no specific geographic routing rule for a particular request, ensuring that traffic is still handled properly.

Use Cases:

- Regional Content Delivery: Serving region-specific content (e.g., different languages or regulations).
- Optimized Performance: Ensuring users are routed to the closest resource for better response times.
- Compliance: Complying with legal or data sovereignty requirements by routing requests based on location.

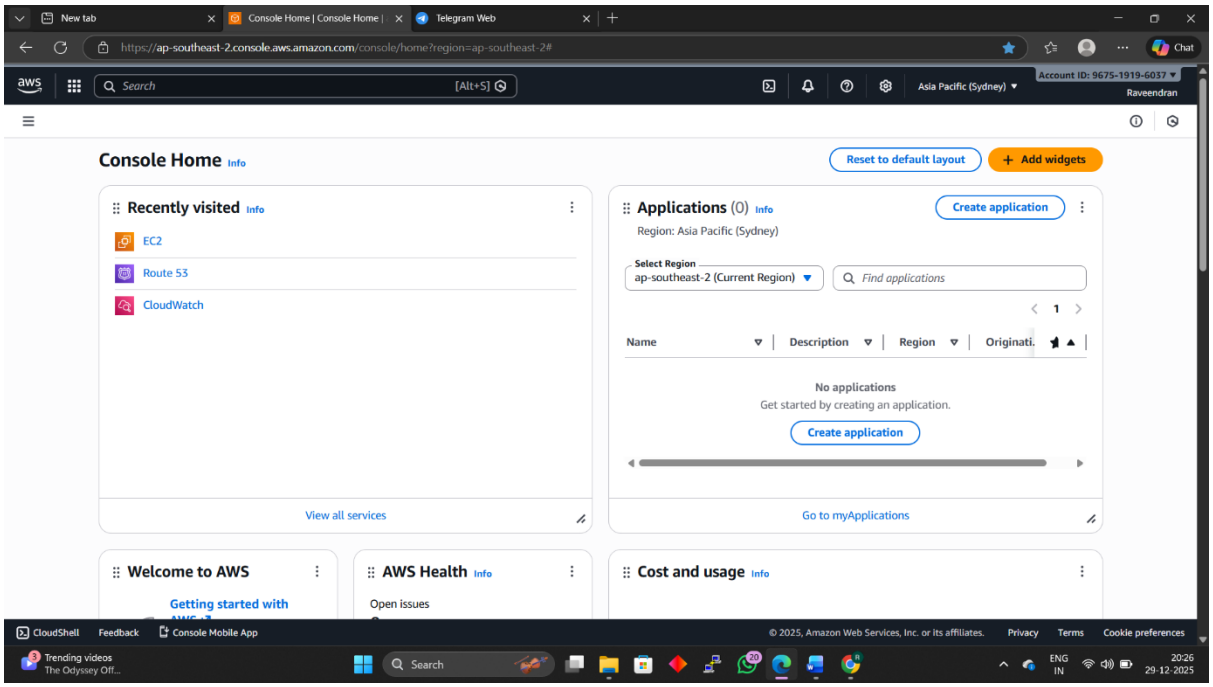
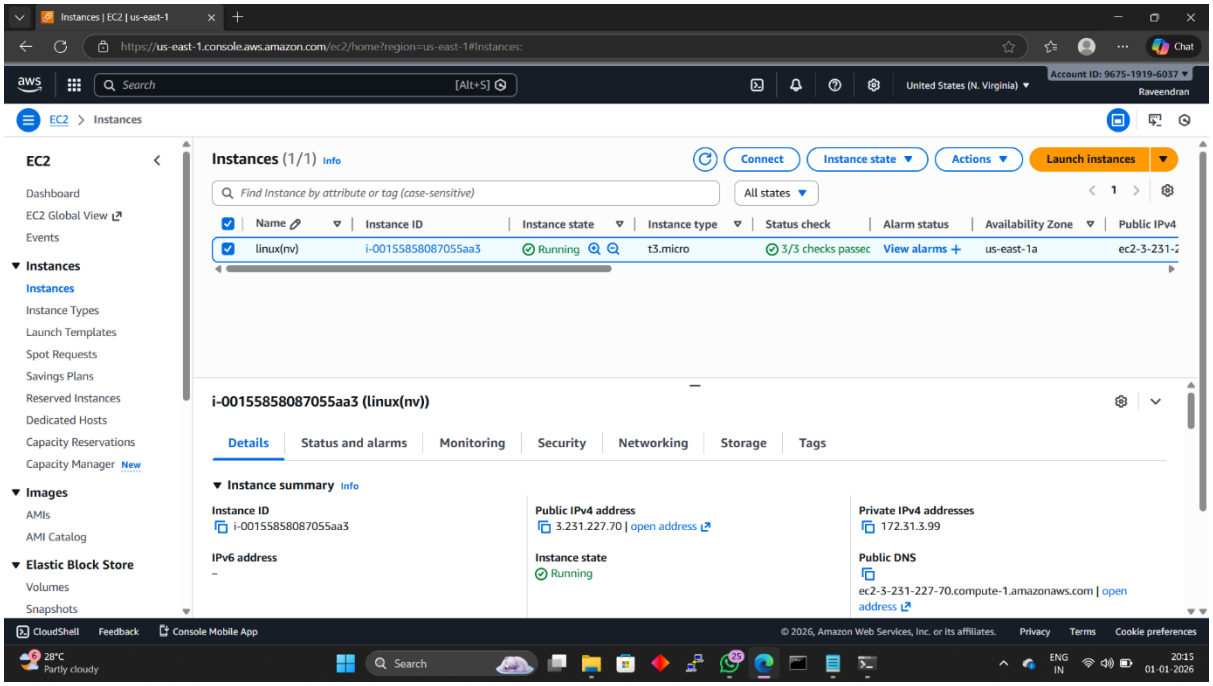
Request from North America Continent Web Clients
Request from Europe Continent Web Clients
Request from Asia Continent Web Clients

Execution Tasks:

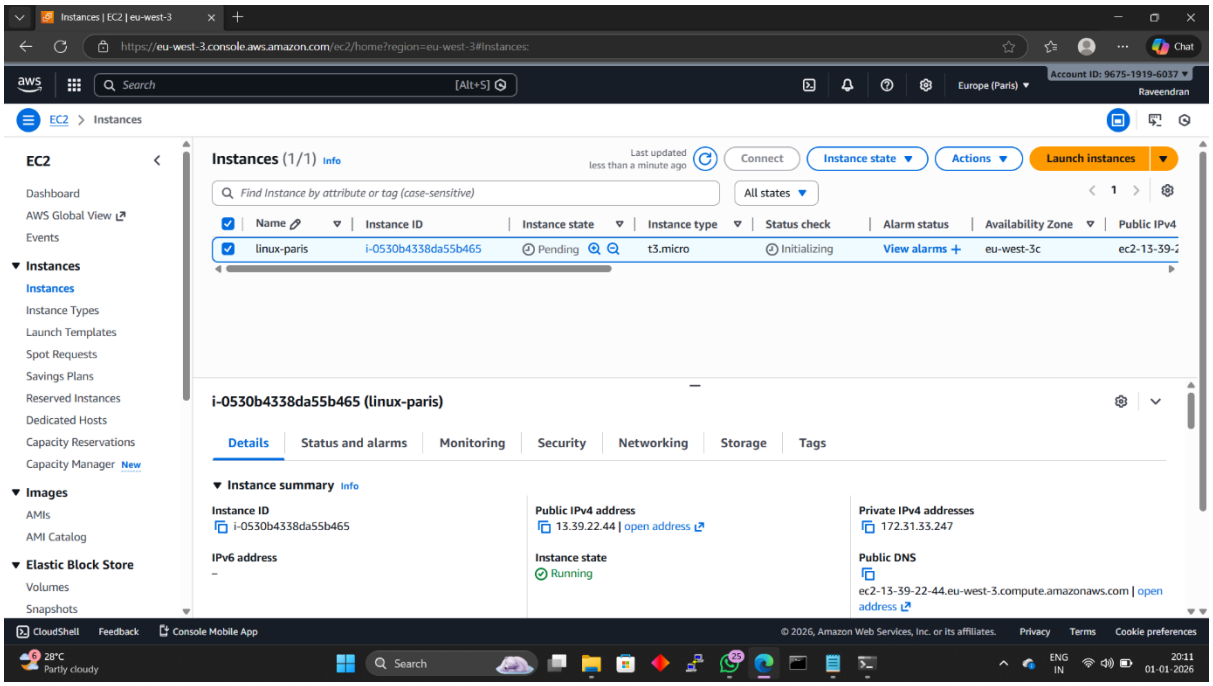
Step 1 : Login in AWS Console.



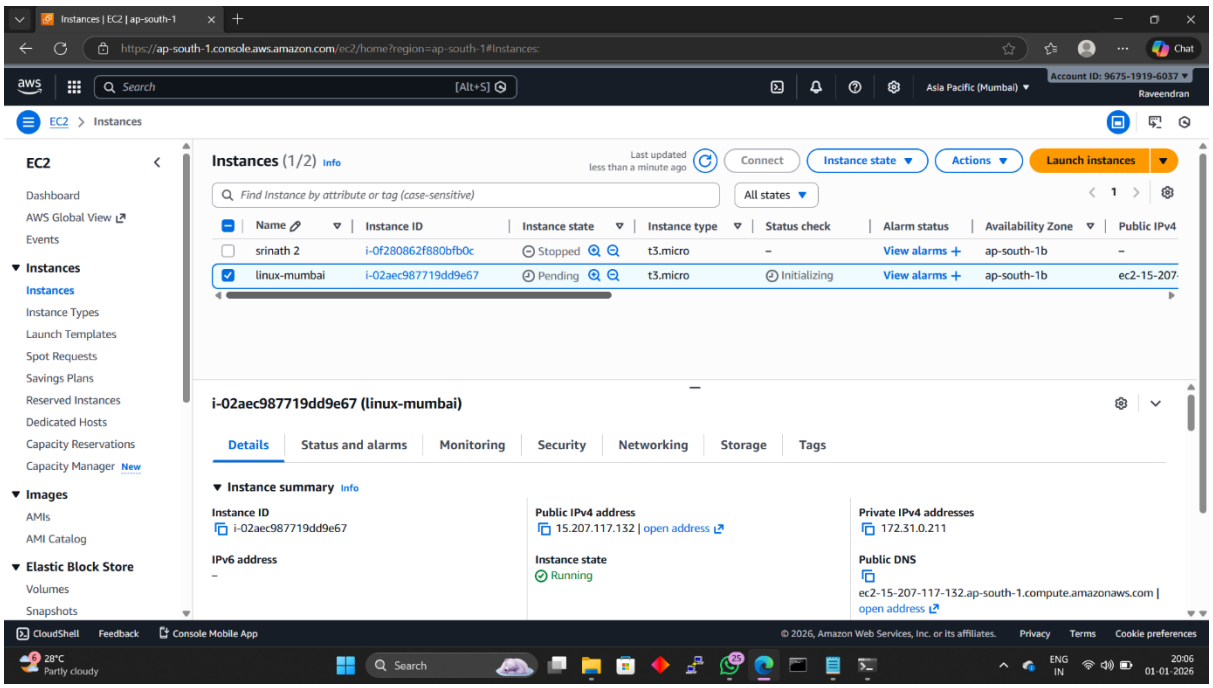
Step 2: Create a Linux Web Server in (Region-North Virginia).



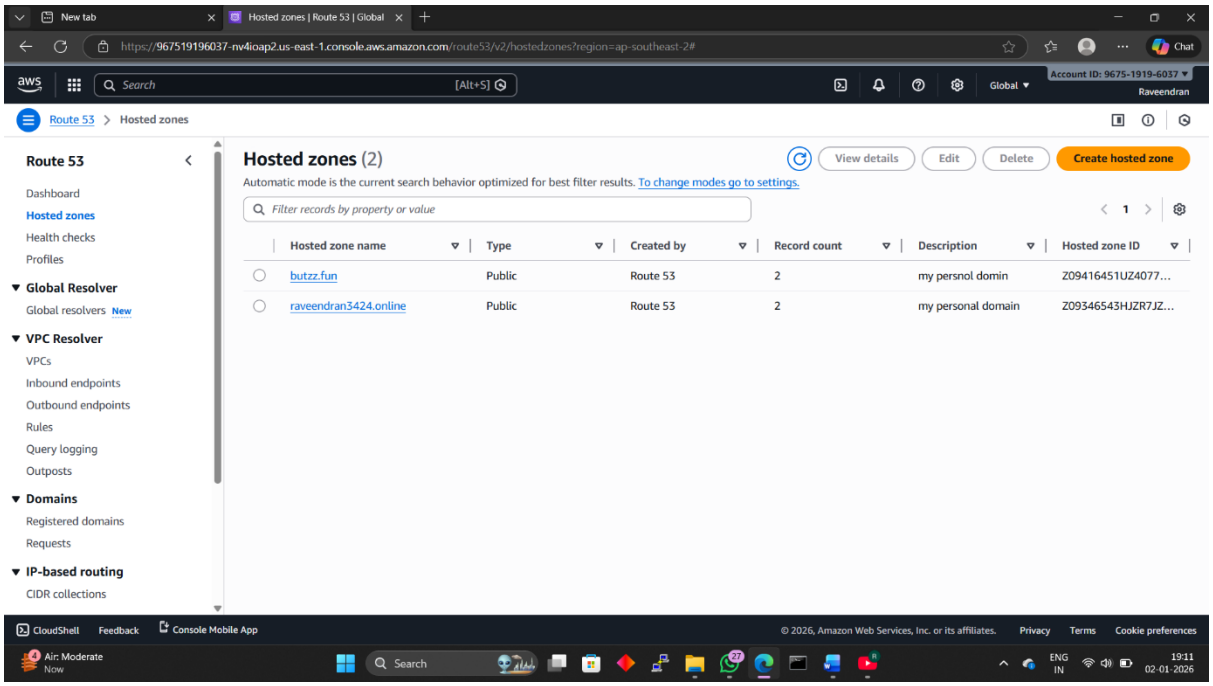
Step 3: Create a Linux Web Server in (Region- Paris).

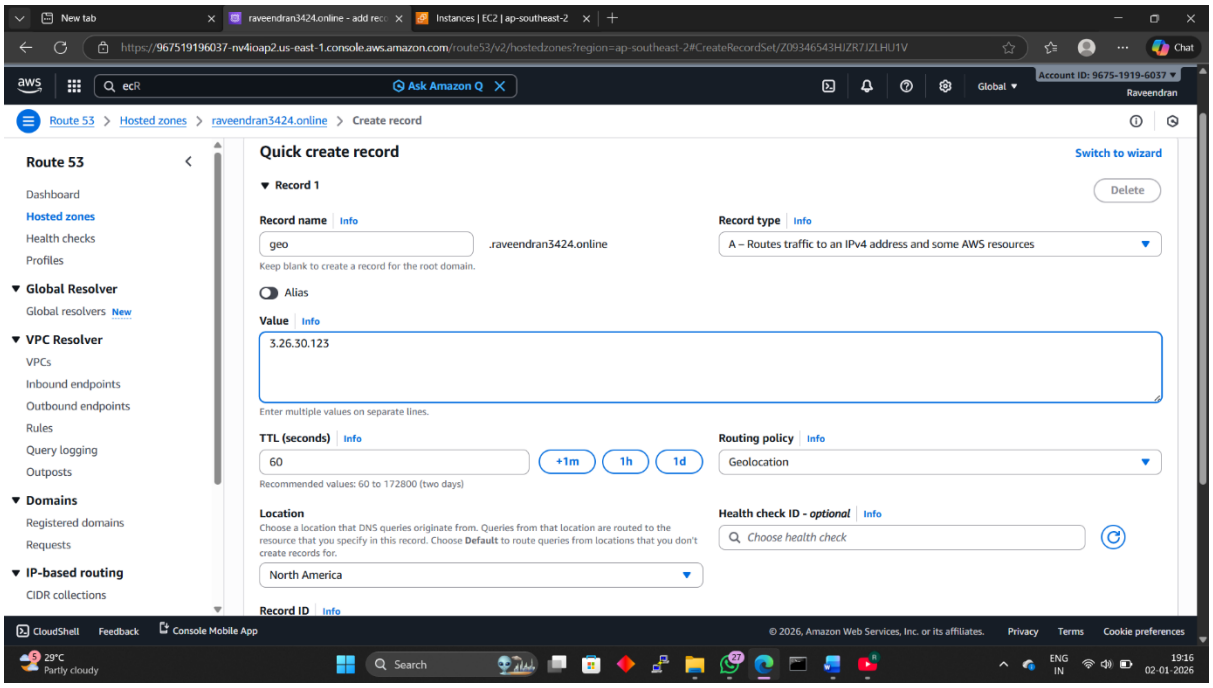


Step 4: Create a Linux Web Server in (Region-Mumbai).



Step 5: Create a Host Zone Records via Route53.





Step 6: The Final Output of all the Web Servers created in different Server.
